

JSON Payload Example [Python Code]

A **request payload** is data (that clients send (to the server) (in the body of an HTTP POST, PUT, or PATCH message)) that contains important information about the request. (To send the JSON with payload to the REST API endpoint) you need to enclose the JSON data (in the body of the HTTP request) and indicate the data type (of the request body) (with the "Content-Type: application/json" request header). If the client expects a response from the server in JSON format, it also needs to send the "Accept: application/json" header to the server. In this JSON Payload Example, we send JSON to the ReqBin echo URL. Click Send to execute the JSON Payload request online and see the results. The Python code was automatically generated for the JSON Payload example.
